

Frequently Asked Questions

Q: Application stops loading at “Loading Configuration”

A: Review C:\inetpub\wwwroot\N20\global\refBaseURL.json to see if settings and JSON syntax are correct. Try to compare the file to a working version using a file compare application.

Basic troubleshooting of NetZoom:

- review application log and NZ20BackgroundTask log in the Event Viewer
- review current IIS log file (C:\inetpub\logs\LogFiles\)
- are services running
- use F12 to see what is failing
- is it an issue with an integration?
 - Check express server <https://n20.netzoom.com/expapi/server/status>
 - check integration parameters
 - is the resource available? Pingable?
 - Can the Application server reach the resource? Possible firewall issue

Q: Application gives a 502 error on startup

A: This can happen after a machine reboot if pm2 is not running. The most common causes are

1. pm2 is not running as a service
2. the pm2 configuration was not saved after installing the Express Servers with the “pm2 save” command

Check to see if pm2 is running. If it is not running but the Express servers have been installed and configured, you may restart them by using these PowerShell commands.

1. cd "<installpath>\expapi"
2. pm2 start 'ecosystem.config.cjs' --only 'exp-api' --env production
3. cd "<installpath>\nzinthumbapi"
4. pm2 start 'ecosystem.config.cjs' --only 'nzinthumb' --env production
5. cd "<installpath>\dcm-listener"
6. pm2 start 'ecosystem.config.cjs' --only 'dcm-listener' --env production

Q: Trouble adding new devices to the data center

A: There are multiple reasons why new devices may not be adding to a datacenter.

1. If the site is a Managed site, you will be prompted to create a workflow when adding devices. The devices are not added to the site until the workflow is executed.
2. Verify that the task service is running and configured properly. Devices are added to NetZoom in two steps. The second step will not complete without using the Background Task Service.

Use the **QA: Task** to verify that the NetZoom Background Task Service is running and see if the Background tasks are "Waiting".

Go to the Windows Service section and see the status of the Background task. If it is not running, use the kebab menu to start the service.

At the top of the task screen, you may filter the tasks by status to ensure that the queue is being processed.

Q: I need help implementing my data center

A: contact support for assistance with implementation and other technical issues
